

October 2014

2014 Kern County Wheat Variety Performance Trial

The 2014 California wheat crop was 560,000 acres including 47,000 acres of durum wheat. Non-durum acreage decreased 106,000 acres from 2013, a 17% decrease. Durum wheat acreage decreased almost 66% since 2012. The multi-year durum acreage average is 104,000 acres with the low and high at 47,000 acres and 176,000 acres in 2014 and 2009, respectively. Over 60 percent of the common wheat acreage was planted to Summit 515 (90,000 acres), WB-Patron (83,000 acres), PR 1404 (63,000 acres), Cal Rojo (48,000 acres), and Joaquin (25,200 acres). This represents a change in variety preference. There were increased plantings of Summit and Patron. Only 15% of the planted acreage was white wheat. Blanca Grande 515 (14,800 acres) led the hard white wheat acreage in the state and the San Joaquin Valley. Orita (9,000) was the leading durum variety. Volante, Fortissimo and Desert King HP were the most widely planted Durum wheat varieties in the San Joaquin Valley representing 82% of the acreage.

Cereal grain variety evaluations were conducted at multiple locations throughout California. The Kern County results are shown in Tables 1 and 2. The tests included advanced breeding lines but only the top yielding experimental varieties is included in these tables. Multi-site/year averages and additional information are included in an Agronomy Progress report published annually. Copies are available at the local county extension office or on the web at

<http://agric.ucdavis.edu/crops/cereals/cereal.htm>.

Varietal differences in Stripe Rust resistance, based on observations from the 2013 University of California statewide variety tests, are as follows:

Common Wheat

Highly Susceptible:

Anza, Joaquin, Mika, Triple IV, FV 2808

Susceptible:

Express, Redwing, PR 1404, Ultra

Resistant:

Blanca Royale, Blanca Grande 515, Cal Rojo, Lassik, New Dirkwin, Patwin, Patwin 515, WB-Patron, WB-Joaquin Oro, WB-Perla

Nitrogen Fertilizer Recommendation Based on Early-Spring Chlorophyll Meter Readings

Nitrogen fertilizer is the most used and often the most mismanaged nutrient input. Nitrogen management has tremendous implications on crop productivity, quality and environmental stewardship. Sufficient nitrogen is needed to optimum yield and quality. Soil and in-season plant tissue testing for nitrogen status are a time consuming and expensive process. Real time sensing of plant nitrogen status can be a useful tool in managing nitrogen inputs. The following is the result of multi-year, multi-location project to assess the usefulness of using chlorophyll meters for making nitrogen fertilizer recommendations in wheat.

Plots at multiple locations in the southern San Joaquin Valley had nitrogen applications of 0, 100, 200, and 300 lbs. nitrogen per acre applied at planting. At growth stage Feekes 5, nitrogen was applied so that each plot had received a total of 300 lbs N/acre. Plant nitrogen status was tested at Feekes 5 and 10 (tillering and flag leaf extension). Plant nitrogen measurements were made by reflectance, transmittance/absorbance, and wet chemistry.

Good correlations ($R^2 > 0.80$) were observed between meter readings and V5 nitrogen concentration (Figure 1). There were some differences between varieties at the different locations. The difference between the meter reading of the well fertilized treatment and the other treatments was calculated.

Grain yields were equivalent for all locations where total nitrogen applied was the same. The total nitrogen applied was greater than the typical amount (50 to 100 lbs N/A depending on yield potential). There was not a decline in yield for over fertilization that can occasionally occur. Once the crop was sufficiently fertilized meter readings became inconclusive and were of no benefit for determining nitrogen status, silage yield and protein and grain yield and protein.

Early season nitrogen fertilizer recommendation is as follows:

Apply the expected full nitrogen fertilizer rate on a reference area at least three weeks prior to sampling where plants are actively growing. The reference area should be representative of the field and can be several small areas throughout the field or a strip through the field. Meter measurements should be made mid leaf on the upper most fully exposed leaf for greatest consistency and accuracy. Plants and leaves that are not representative of the field, under stress or insect damaged should not be sampled. At Feekes 5 to 6, compare the readings from the reference areas to readings from the remainder of the field. Because individual plants vary, at least 30 readings should be made throughout the field and reference area. The difference between the averages of the readings will give an indication of the need for additional nitrogen fertilizer.

The nitrogen rate calculation is: $N = 40 + 14D$ using the SPAD meter
 $N = 20 + 12D$ using the CCM 200 meter

Where:

N = Recommended Nitrogen Rate in lbs N/A

D = Difference in meter reading between measured crop and reference area

As an example, if the average meter reading between the fertilizer reference sites and the field was 10, then the recommendation nitrogen fertilizer rate would be $40 + (14 * 10)$ for a total of 180 lbs N/A.
